system calls fork and wait.

```
Program 1: main {val = 5;
if(fork()) wait(&val);
val++; printf("%d\n", val);
return val;}
```

```
Program 2:
main() {val = 5; if(fork())
wait(&val); else exit(val);
val++; printf("%d\n", val);
return val; }
```

In the first program, the parent process creates a child and then waits for the child to exit (through the system call "wait").

Solution Operating System Concepts By Galvin, Silberschatz Solved By Abhishek Pharkya Part 1: Theory What is the primary difference between a kernel-level context switch between processes (address spaces) and a user-level context switch? The primary difference is that kernel-level context switches involve execution of OS code. As such it requires crossing the boundary between user- and kernel-land two times.

to the critical-section
problem A solution to the
critical-section problem
must satisfy the following
three requirements:

- Mutual exclusion. If process P_i is executing in its critical section, then no other processes can be executing in their critical sections.
- Progress. If no process is executing in its ...

5.24 Silberschatz, Galvin and Gagne ©2013 Operating System Concepts - 9 th Edition Turnaround Time Varies With The Time Quantum The average turnaround time of a set of processes does not necessarily improve as the time-quantum size increases. In general, the average turnaround time can be improved if most processes finish their next CPU burst in a single time quantum.

Answer: Clustered systems are typically constructed by combining multiple computers into a single system to perform a computational task distributed across the cluster. Multiprocessor systems on the other hand could be a single physical entity comprising of multiple CPUs. A clustered system is less tightly coupled than a multiprocessor system.
